

ABSTRACT OF THE DISCLOSURE

An enteral nutrition product is disclosed which is formed as a semi-solid. The semi-solid is common to a solid in that 5 the semi-solid has a shape retentivity allowing a shape of the semi-solid to be retained without a spontaneous change in shape, and in that the semi-solid is capable of containing a nutrition component at a higher concentration than those of a liquid and a fluid. On the other hand, the semi-solid is common to the liquid 10 and the fluid in that the semi-solid is easier to be changed in shape due to an externally forced load than the solid. The shape retentivity is maintained before, during, and after administration of the enteral nutrition product into the patient, and is maintained while the enteral nutrition product 15 is stayed within the patient, such that the enteral nutrition product is not liquefied due to a body temperature of the patient.
